

Human Assets Index

Computing retrospective series from 1970 to 2008

Catherine KORACHAIS

1. Introduction

The United Nations Committee for Development Policy (CDP) defines the Least Developed Countries (LDCs) as countries suffering from structural handicaps to economic development such as low income, low levels of human resources or capital, and high levels of structural economic vulnerability (UN 2008). The identification of LDCs is carried out according to predetermined thresholds on the three following criteria:

- (a) Gross National Income per capita (GNI per capita)
- (b) Human Assets Index (HAI)
- (c) Economic Vulnerability Index (EVI)

Here we are interested in the level of human capital. The latter was initially measured by literacy rates, which was insufficient since it didn't take into account health levels. Then it was replaced from 1991 to 2002 by the Augmented Physical Quality of Life Index (APQLI). Since 2003, it was replaced by the Human Assets Index (HAI), which is more complete (for a historical review, cf. Guillaumont 2009, *Caught in a trap*, chap. 5).

1 Introduction

The United Nations Committee for Development Policy (CDP) defines the Least Developed Countries (LDCs) as countries suffering from structural handicaps to economic development such as low income, low levels of human resources or capital, and high levels of structural economic vulnerability (UN 2008). The identification of LDCs is carried out according to predetermined thresholds on the three following criteria:

- (a) Gross National Income per capita (GNI per capita)
- (b) Human Assets Index (HAI)
- (c) Economic Vulnerability Index (EVI)

Here we are interested in the level of human capital. The latter was initially measured by literacy rates, which was insufficient since it didn't take into account health levels. Then it was replaced from 1991 to 2002 by the Augmented Physical Quality of Life Index (APQLI). Since 2003, it was replaced by the Human Assets Index (HAI), which is more complete (for a historical review, cf. Guillaumont 2009, *Caught in a trap*, chap. 5).

The HAI refers to factors that improve the productivity of people, namely education and health. Indeed, education and health increase productivity: a well-educated worker can better understand work instructions; besides, with a poor health, even the most educated workers are unable to reach their maximum potential productivity. Thus, while taking into account the components of well-being, HAI is concerned with capacity or with "capability" (Sen 1997).

So far, three triennial reviews of HAI data have been completed and made available by the CDP and the DESA: reviews 2003, 2006 and 2009. These are cross-sectional data over the recent period. The 2006 and 2009 reviews provide HAI values for 130 developing countries, including all LDCs. However these data do not allow for comparisons over time. Even if the 2006 review applies the same method as that of the 2009 review, time comparisons are relatively limited, since the 2009 review is rather an update of the 2006 data. To overcome that and to get the possibility to observe the evolution of human disabilities in developing countries (LDCs and non LDCs) over time, we propose here to set up annual HAI series over the 1970-2008 period. The definition of the index remains identical over time, making time comparisons possible.

This work raises several challenges. The main one is that the statistics on the HAI components are not always available. This is especially true for old data and/or for data from developing countries that do not have adequate national statistical institutes. The challenge is then to fill with consistency the lack of statistics. This leads us to set up two different sets of HAI series. One is built on the basis of official but incomplete statistics. This dataset is called "HAI FOS", for "From Official Sources". The other one fills in the gaps and extends the dataset with the help of econometric estimates. We call it "HAI WFG", for "With Filled Gaps".

This document presents the methods used to build these databases. Section 2 recalls the HAI definition and its calculation, according to the *Handbook on the Least Developed Country Category* (UN 2008). Section 3 presents for each indicator the methods used to obtain complete retrospective series from 1970 to 2008. Section 4 presents the results of HAI and its components, and provides a descriptive analysis of the evolution of this indicator in the LDCs and in the rest of the world. Finally Section 5 concludes.

2 HAI definition and calculation

The HAI provides information on the level of human capital development. It is a combination of four indicators related both to the level of health and nutrition and to the level of education. It consists in two indicators for health and nutrition:

- Index of child mortality rate (CS)
- Index of prevalence of undernourishment in the population (CI)

And two for education:

- Index of adult literacy rate (LR)
- Index of gross enrolment in secondary education (SE)

The HAI is calculated as the simple average of the component indices: the original component data are transformed into indices between 0 and 100, applying min-max procedures (as described below) based on the minimum and maximum values of a basket of reference countries. However, normalization based on min and max values raises the question of possible distortions in the case of extended tails of distributions. To overcome this and prevent the presence of outliers, lower and upper bounds are determined to replace the minimum and maximum observed values: this procedure allows for better comparisons.

2.1 The choice of components

Undernourishment compromises health status and educational achievement, and thereby has an important negative impact on productivity. Similarly, the under-five mortality rate reflects the social, economic and environmental conditions in which children, and by extension the overall population, live. It also approximates the health status of the population as a whole: for low-income countries, life expectancy of the population tends to be strongly correlated with rates of child mortality¹.

A low level of education is also a major obstacle to development as it implies an overall shortage of skills for the organization and functioning of the economy, and reflects a low capacity to absorb technological advances. Achievements in education are measured by the adult literacy rate and the gross secondary enrolment ratio. Adult literacy indicates the available basis for enlarging the trained and skilled human resources needed for development. The gross secondary enrolment ratio complements this information by providing indication of the share of population with a certain level of skills. This indicator is preferred to the average years of schooling of the active population since its reliability is limited, or to the primary enrolment ratio since it is already reflected by the literacy rate (UN 2008).

2.2 The normalization of components

The original data of these four variables are converted into index numbers, using the min-max procedure, and rescaled to remove significant outliers as described below. The resulting indices are bounded between 0 and 100 and can be interpreted positively (*i.e.: the closer the indices to 100, the better the health or education assets*).

Min-max procedures

For child mortality rates (U5MR) and for undernourishment prevalence, we proceed as follows:

$$CS \text{ or } CI = \begin{cases} \frac{(Max-x)}{(Max-min)} \cdot 100 & \text{if } min < x < Max \\ 100 & \text{if } x < min \\ 0 & \text{if } x > Max \end{cases}$$

with x = U5MR or undernourishment prevalence value (respectively)

¹ The CDP recognizes that the child mortality rate gives an incomplete picture of the health of the entire population. For instance, to better reflect the impact of HIV/AIDS, which has expanded rapidly in low-income countries and has a negative impact on human resources, the CDP would have preferred an indicator such as life expectancy, as an alternative to the child mortality rate. However, studies tend to show that child mortality is a good global health indicator since it depends on access to drugs and health services, access to water and sanitation of quality, mothers' health, and exposition of mothers and children to illness, etc. Besides, even if it is focused on the youngest part of the population, child mortality is much more reliable than life expectancy at birth. Indeed, data on adult mortality in developing countries often remain unknown. Estimates of life expectancy at birth are then often realized with the help of modelisations based on data relative to other populations, and are finally not as reliable as are child mortality rates.

And for literacy and secondary gross enrolment rates:

$$LR \text{ or } SE = \begin{cases} \frac{(x-min)}{(Max-min)} \cdot 100 & \text{if } min < x < Max \\ 0 & \text{if } x < min \\ 100 & \text{if } x > Max \end{cases}$$

with x= literacy or secondary gross enrolment rates (respectively).

Lower and upper bounds

Rather than using the minimum and maximum values of the series, in order to prevent the presence of outliers, predetermined upper and lower bounds are used, and are reported in the following table.

Table 2.1 Bounds used for the calculations of the component indices

	Lower bound	Upper bound
	<i>min</i>	<i>Max</i>
U5M	10	240
% undernourishment	2.5	65
Literacy rate	15	100*
Sec. gross enr. rate	5.7	100

Source: United Nations 2008, Guillaumont 2010. Note: * upper bound set at 99.8 by United Nations 2008.

These bounds have been recently set by the United Nations (2008), from a reference basket of 130 developing countries (incl. all LDCs), for the 2006 HAI review. The first extreme value for which the distance to the nearby observation is lower than or equal to the standard deviation of the series is used as a bound.

2.3 HAI computation

The HAI is the arithmetic average of the four indices described above:

$$HAI = \frac{CS + CI + LR + SE}{4}$$

3 Computing the retrospective HAI

Calculating the HAI retrospectively requires the availability of historical data on the four variables composing the HAI, i.e. on the child mortality rate, the prevalence of undernourishment, the literacy rate and the gross enrolment ratio in secondary education. In this section, we report the availability of these data and the methods adopted to generate the missing values.

Two HAI databases are proposed: the *From Official Sources – FOS HAI* database, and the *With Filled Gaps – WFG HAI* database. In the latter, missing data are replaced by data generated from regressions using per capita income, time trend and/or fixed effects country or region; it provides a general overview of the HAI in the developing world over time, but is not recommended for econometric analysis, or only very cautiously.

3.1 Under-five mortality rate

Definition

The under-five mortality rate refers to the probability of dying before 5 years, per 1,000 newborns.

Data availability

The *World Population Prospects*, UNDP, i.e. the data source used for the official HAI reviews, does not provide information on child mortality before 1995. Then, other data sources are considered for the collection of retrospective data on under-five mortality rates:

- The five-year data of Ahmad, Inoue and Lopez (2000) cover almost all countries of the world in 1955-1999.
 - UNICEF Child info (2010) data are the result of the work of the Inter-agency Group for Child Mortality Estimation² (IGME), and are available for a large number of countries from 1960 to 2008:
- | | | | | | | | | |
|--------------|------|------|------|------|------|------|------|------|
| Year | 1960 | 1970 | 1980 | 1990 | 1995 | 2000 | 2005 | 2008 |
| Nb countries | 99 | 135 | 175 | 192 | 194 | 194 | 194 | 194 |

Method

The most accurate, complete and actualized data are those of the IGME, provided by UNICEF Child info. Missing values are measured by linear interpolation. When interpolation is not possible, the five-year data of Ahmad, Inoue and Lopez (2000) are used since they are consistent with the UNICEF Child Info data.

The resulting series contains data for 150 developing countries, incl. all countries of the HAI 2009 review. Only some countries present some gaps:

- | | |
|---|---|
| - Antigua and Barbuda, 1970 to 1994 | - St Vincent and the Grenadines, 1970 to 1979 |
| - Federate States of Micronesia, 1970 to 1989 | - Saint Lucia, 1970 to 1979 |
| - Grenada, 1970 to 1989 | - Timor-Leste, 1970 to 1989 |
| - Palau, de 1970 à 1979 | - Tuvalu, 1970 to 1979 |
| - Saint Kitts and Nevis, 1970 to 1979 | - West Bank and Gaza, 1970 to 1979 |

For the HAI WFG, the following methods of estimation are applied in order to fill in these gaps.

■ Method no. 1

The method of imputation for missing values is to substitute generated data of under-five mortality rates from econometric fixed-effect estimator (*Within*). Among other things, this method allows taking into account characteristics that are specific to the country. We apply the following model on the whole sample:

$$(3.1.1) \quad \log(U5M_{it}) = \alpha_1 + \beta_1 \cdot \log(GNIpc_{it}) + \gamma_{1t} \cdot t + \mu_{1i} + \varepsilon_{1it}$$

Où : α_1 constant

β_1 Coefficient of GNI per capita

γ_{1t} Coefficient of time dummy t

μ_{1i} Fixed effects of country i

ε_{1it} Error term

Then, missing values are substituted by predicted values in the following manner:

$$(3.1.2) \quad \widehat{U5M}_{it} = \exp(\alpha_1 + \beta_1 \cdot \log(GNIpc_{it}) + \gamma_{1t} \cdot t + \mu_{1i})$$

Results of model (3.1.1) are available in Table D.1 (Appendix D). The explanatory power of regression 3.1.1 is 77%, which is relatively high and allows the imputation for missing values.

² This brings together: UNICEF, WHO, The World Bank and United Nations Population Division.

■ Method no. 9

Method no. 1 cannot be applied for countries with no information on GNI per capita. This is the case for the Timor-Leste between 1970 and 1989. Since this country is a sovereign state³ only since 2002, and as U5MR data do not present any similarity between Timor-Leste and its neighbor Indonesia, we do not generate data for Timor-Leste for 1970-89.

3.2 Prevalence of undernourishment

Definition

The prevalence of undernourishment is the proportion of the total population in a condition of undernourishment. Undernourishment refers to the condition of people whose dietary energy consumption is continuously below a minimum dietary energy requirement for maintaining a healthy life and carrying out a light physical activity (source: FAO Statistics Division – metadata).

Data availability

Availability of data on prevalence of undernourishment provided by the FAO Statistics Division (2010) is as follows:

Period	90-92	95-97	00-02	04-06
Nb countries	109	110	102	98

There is no information on the prevalence of undernourishment before 1990. However, we can assess it by using information on the mean levels of daily dietary energy consumption (available yearly from 1961 to 2005, FAO Food Balance Sheets, 2010) and, when possible, on income distribution (like the Gini coefficient, available every 3 years in 1981-2005, PovcalNet dataset, World Bank, 2009). For 2007 and 2008, since there is no information on the dietary intake, we there extrapolate series with some other controls.

Method

The FOS HAI database is set up with primary FAO data as well as values assessed with methods 1 to 4. The WFG HAI dataset substitutes values that have been generated with methods 5 to 8.

■ Method no. 1

The first method uses information on the average daily level of kilocalories consumption per capita and on income distribution (approximated by the Gini coefficient). The following model is estimated using the *Within* estimator:

$$(3.2.1) \quad U_{it} = \alpha_1 + \beta_1 \cdot \overline{kcal}_{it} + \gamma_1 \cdot Gini_{it} + \mu_{1i} + \varepsilon_{1it}$$

with U_{it} prevalence of undernourishment in country i over year t

\overline{kcal}_{it} mean level of energy supply, in kilocalories per capita and per day, in country i during year t

$Gini_{it}$ Gini coefficient

μ_{1i} country fixed-effects

ε_{1it} error term

Then, coefficients α_1 , β_1 , γ_1 and μ_{1i} are taken out and used to generate values with method no. 1:

$$(3.2.2) \quad \hat{U}_{1it} = \alpha_1 + \beta_1 \cdot \overline{kcal}_{it} + \gamma_1 \cdot Gini_{it} + \mu_{1i}$$

³ Timor-Leste was colonized by Portugal until 1975, then it was occupied by Indonesia.

■ Method no. 2

The second method is similar to method no.1 but is applied when data on Gini coefficient are missing: the following model is estimated with the *Within* estimator:

$$(3.2.3) \quad U_{it} = \alpha_2 + \beta_2 \cdot \overline{kcal}_{it} + \mu_{2i} + \varepsilon_{2it}$$

With U_{it} prevalence of undernourishment in country i over year t
 \overline{kcal}_{it} mean level of energy supply, in kilocalories per capita and per day, in country i during year t
 $Gini_{it}$ Gini coefficient
 μ_{2i} country fixed-effects
 ε_{2it} error term

Coefficients α_2, β_2 and μ_{2i} are taken out and used to calculate missing values with method no.2:

$$(3.2.4) \quad \hat{U}_{2it} = \alpha_2 + \beta_2 \cdot \overline{kcal}_{it} + \mu_{2i}$$

■ Method no. 3

Methods no. 3 and no. 4 estimate values occurring in the ending parts of time series by using the lagged prevalence of undernourishment. Method no. 3 applies the following model:

$$(3.2.5) \quad U_{it} = \alpha_3 + \beta_3 \cdot U_{i,t-1} + \gamma_3 \cdot GNIpc_{it} + \delta_3 \cdot Gini_{it} + \mu_{3i} + \varepsilon_{3it}$$

With U_{it} prevalence of undernourishment in country i over year t
 $GNIpc_{it}$ GNI per capita
 $Gini_{it}$ Gini coefficient
 μ_{3i} country-fixed effects
 ε_{3it} error term

Coefficients $\alpha_3, \beta_3, \gamma_3, \delta_3$ and μ_{3i} are taken out and used to calculate missing values with method no.3:

$$(3.2.6) \quad \hat{U}_{3it} = \alpha_3 + \beta_3 \cdot U_{i,t-1} + \gamma_3 \cdot GNIpc_{it} + \delta_3 \cdot Gini_{it} + \mu_{3i}$$

■ Method no. 4

Method no. 4 is used for the same purpose, but for countries with no information on the Gini coefficient; it applies the following model:

$$(3.2.7) \quad U_{it} = \alpha_4 + \beta_4 \cdot U_{i,t-1} + \gamma_4 \cdot GNIpc_{it} + \mu_{4i} + \varepsilon_{4it}$$

With U_{it} prevalence of undernourishment in country i over year t
 $GNIpc_{it}$ GNI per capita
 $Gini_{it}$ Gini coefficient
 μ_{4i} country-fixed effects
 ε_{4it} error term

Coefficients $\alpha_4, \beta_4, \gamma_4$ and μ_{4i} are taken out and used to calculate missing values with method no.4:

$$(3.2.8) \quad \hat{U}_{4it} = \alpha_4 + \beta_4 \cdot U_{i,t-1} + \gamma_4 \cdot GNIpc_{it} + \mu_{4i}$$

Results of the estimations of models (3.2.1), (3.2.3), (3.2.5) and (3.2.7) are presented in Table D.2 (appendix D). The FOS HAI database is constituted of data sources as well as estimates resulting from methods no.1, 2, 3 and 4. The methods which are following (no. 5 to no.9) concern only the WFG HAI database.

■ Method no. 5

For missing values, we first apply the method also used for the under-five mortality rate estimates, i. e. we estimate the prevalence of undernourishment with econometric regressions, taking into account income level and inequalities, time and country effects. The following model is estimated with the *Within* estimator:

$$(3.2.9) \quad U_{it} = \alpha_5 + \beta_5 \cdot \ln(GNIpc_{it}) + \gamma_5 \cdot \ln(Gini_{it}) + \delta_{5t} \cdot t_t + \mu_{5i} + \varepsilon_{5it}$$

Coefficients $\alpha_5, \beta_5, \gamma_5, \delta_5$ and μ_{5i} are taken out and used to calculate missing values with method no.5:

$$(3.2.10) \quad \hat{U}_{it} = \alpha_5 + \beta_5 \cdot \ln(GNIpc_{it}) + \gamma_5 \cdot \ln(Gini_{it}) + \delta_{5t} \cdot t_t + \mu_{5i}$$

This method concerns Bosnia and Herzegovina, Croatia, the FYROM and Malaysia in 1970-89, since they do not provide information on energy supply for this period.

■ Method no. 6

Method no.6 applies almost the same model to countries that do not have any information on the prevalence of undernourishment neither on the energy supply on the whole period 1970-2008. For them, the *Within* estimator cannot be used, and we cannot get country-fixed effects. Then, we rather exploit region fixed-effects, and we assess the following model with the OLS estimator:

$$(3.2.11) U_{it} = \alpha_6 + \beta_6 \cdot \ln(GNIpc_{it}) + \gamma_6 \cdot \ln(Gini_{it}) + \delta_{6t} \cdot t_t + \mu_{6i} \cdot region_i + \varepsilon_{6it}$$

Coefficients $\alpha_6, \beta_6, \gamma_6, \delta_6$ and μ_{6i} are taken out and used to calculate missing values with method no.6:

$$(3.2.12) \hat{U}_{it} = \alpha_6 + \beta_6 \cdot \ln(GNIpc_{it}) + \gamma_6 \cdot \ln(Gini_{it}) + \delta_{6t} \cdot t_t + \mu_{6i} \cdot region_i$$

This method concerns Bhutan and Papua New Guinea for the whole period 1970-2008.

■ Method no. 7

For missing values for which there is no observation on the Gini coefficient, we apply correlates of methods no.5 and no.6, but without the Gini coefficient. Method no.7 proposes to estimate the following model with the *Within* estimator:

$$(3.2.13) U_{it} = \alpha_7 + \beta_7 \cdot \ln(GNIpc_{it}) + \delta_{7t} \cdot t_t + \mu_{7i} + \varepsilon_{7it}$$

Then the prevalence of undernourishment is assessed:

$$(3.2.14) \hat{U}_{it} = \alpha_7 + \beta_7 \cdot \ln(GNIpc_{it}) + \delta_{7t} \cdot t_t + \mu_i$$

This method concerns Montenegro, Serbia and West Bank and Gaza in 1970-89.

■ Method no. 8

Finally, as for method no.6, method no.8 concerns countries that do not have any information on the prevalence of undernourishment neither on the energy supply on the whole period 1970-2008; furthermore, it concerns countries that do not have information on income inequalities. For them, the following model is applied with the OLS estimator:

$$(3.2.15) U_{it} = \alpha_8 + \beta_8 \cdot \ln(GNIpc_{it}) + \delta_{8t} \cdot t_t + \mu_{8i} \cdot region_i + \varepsilon_{8it}$$

Then the prevalence of undernourishment is assessed:

$$(3.2.16) \hat{U}_{it} = \alpha_8 + \beta_8 \cdot \ln(GNIpc_{it}) + \delta_{8t} \cdot t_t + \mu_{8i} \cdot region_i$$

This method concerns Afghanistan, Federal States of Micronesia, Equatorial Guinea, Iraq, Marshall Islands, Oman, Palau, Somalia, Tonga, and Tuvalu, over the whole period 1970-2008.

Table D.3 (in appendix D) present the results of estimates of models (3.2.9), (3.2.11), (3.2.13) and (3.2.15) that respectively rely to methods no. 5, 6, 7, and 8.

■ Method no. 9

Method no.9 is with no imputation, leaving missing values. In the case of the prevalence of undernourishment, it concerns ex-USSR countries in 1970-89, since we do not have information on their energy supply in kilocalories, neither on their income level. Consequently, we have missing values in 1970-89 for Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Lithuania, Latvia, Moldova, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan.

3.3 Literacy rate

Definition

The literacy rate is the percentage of population of a given age range who can both read and write with understanding a short simple statement on their everyday life. Generally, 'literacy' also encompasses 'numeracy', the ability to make simple arithmetic calculations (Source: UNESCO Institute for Statistics glossary).

Data availability

The UNESCO Institute for Statistics regularly collects data on literacy and actualizes the related statistics and estimates twice a year, in April and in September. Statistics are available for almost all countries. The most recent and actualized data are provided by the Data Centre (online on their website); historical data are available in the Archives (also online).

■ Data Centre data

In the Data Centre database, 149 countries do have at least one observation on the period 1975-2007.

■ Archives data

The “Literacy Statistical Archives” category of the UNESCO Institute for Statistics provides on its website a collection of historical data on literacy. Two datasets are of interest:

- A dataset of data on literacy rate for the period 2000-2004, estimated in April 2006;
- A dataset of data on literacy rate for many countries and for years 1970, 1980, 1990, 1995, 2000, 2005, 2010, 2015; estimated in 2002 and actualized in 2005.

Method

Data Centre data are used as primary source and Archives data are used as secondary (for those estimated in 2006) and as tertiary (for those actualized in 2005). First, interpolation between values is done with primary data. For data that remains missing, the secondary data and then the tertiary data are used to do the interpolation⁴.

These data constitute the FOS HAI dataset. The following methods allow estimating missing values and concern only the WFG HAI dataset.

■ Method no. 1

For values missing in the ending parts of series, after 2004, we first apply econometric estimates taking into account income level, time and country fixed effects, as well as the lagged value of literacy. The *Within* estimator is applied to the following model:

$$(3.3.1) \text{Lit}_{it} = \alpha_1 + \beta_1 \cdot \ln(\text{GNIPC}_{it}) + \gamma_1 \cdot \text{Lit}_{i,t-1} + \delta_{1t} \cdot t_t + \mu_{1i} + \varepsilon_{1it}$$

Imputed value for missing literacy rate is then the predicted value (first for 2005, then for 2006, etc.):

$$(3.3.2) \widehat{\text{Lit}}_{it} = \alpha_1 + \beta_1 \cdot \ln(\text{GNIPC}_{it}) + \gamma_1 \cdot \text{Lit}_{i,t-1} + \delta_{1t} \cdot t_t + \mu_{1i}$$

■ Method no. 2

Method no. 2 generates values missing before 2004. It applies the same method as the no.1, but without the lagged value of literacy:

$$(3.3.3) \text{Lit}_{it} = \alpha_2 + \beta_2 \cdot \ln(\text{GNIPC}_{it}) + \delta_{2t} \cdot t_t + \mu_{2i} + \varepsilon_{2it}$$

Literacy rate assessment is then calculated:

$$(3.3.4) \widehat{\text{Lit}}_{it} = \alpha_2 + \beta_2 \cdot \ln(\text{GNIPC}_{it}) + \delta_{2t} \cdot t_t + \mu_{2i}$$

■ Method no. 3

Method no. 3 concerns series that have only one observation of literacy over 1970-2008, so that we cannot get country fixed-effects estimates using a *Within* estimator. We then add region fixed effects to model (3.3.1) and estimate it with the *OLS* estimator:

$$(3.3.5) \text{Lit}_{it} = \alpha_3 + \beta_3 \cdot \ln(\text{GNIPC}_{it}) + \delta_{3t} \cdot t_t + \mu_{3i} \cdot \text{region}_i + \varepsilon_{3it}$$

Literacy rate is then computed as:

$$(3.3.6) \widehat{\text{Lit}}_{it} = \alpha_3 + \beta_3 \cdot \ln(\text{GNIPC}_{it}) + \delta_{3t} \cdot t_t + \mu_{3i} \cdot \text{region}_i$$

This method concerns Bhutan, Tonga and Sao Tome and Principe.

⁴ Estimated values of 2010, which are approximate and provided by the tertiary data source, are not taken into account and then are not used for interpolation, when they are not consistent with the trend observed in the 2000s with data provided by the Data Centre.

■ Method no. 4

Imputed values for missing data in the beginning part of the Bhutan time series are generated by using the relative deviation with Nepal series. Indeed, Bhutan and Nepal are neighbor countries and all their series do look alike. We first calculate a ratio between Bhutan literacy and Nepal literacy in 2005 (year for which Bhutan has information on its literacy rate):

$$(3.3.7) \text{Ratio} = \frac{Lit_{Bhutan,2005}}{Lit_{Nepal,2005}}$$

We then apply this ratio for Bhutan missing values in 1970-2004:

$$(3.3.8) Lit_{Bhutan,t} = \text{ratio} \cdot Lit_{Nepal,t}$$

■ Method no. 5

For countries that do not have any information on literacy over 1970-2008, we assess it by estimating the following model with the OLS estimator:

$$(3.3.9) Lit_{it} = \alpha_5 + \delta_{5t} \cdot t_t + \mu_{5i} \cdot region_i + \varepsilon_{5it}$$

Literacy rate is then generated by:

$$(3.3.10) \widehat{Lit}_{it} = \alpha_5 + \delta_{5t} \cdot t_t + \mu_{5i} \cdot region_i$$

This method concerns Dominica, Federate States of Micronesia, Georgia, Grenada, Kiribati, Saint Kitts and Nevis, Marshall islands, Solomon islands, Somalia, Timor Leste, Tuvalu, and Saint Vincent and the Grenadines.

Table D.4 (in appendix D) presents the results of estimates of models (3.3.1), (3.3.3), (3.3.5) and (3.3.9) that respectively rely to methods no. 1, 2, 3, and 5.

■ Method no. 9

Method no. 9 concerns missing values that cannot be replaced by generated values:

- Azerbaijan, Georgia, Kyrgyzstan, Turkmenistan, and Timor-Leste in 1970-89; they remain missing since they do not have information on GNI per capita;
- The beginning of series of Antigua and Barbuda (before 2004) and of Palau (before 1980) as well as the entire series of North Korea.

3.4 Secondary enrolment rate

Definition

Gross secondary enrolment rate is the total number of pupils enrolled in secondary level of education, regardless of age, expressed as a percentage of the eligible official school-age population corresponding to the secondary level of education in a given school year.

A high secondary enrolment rate generally indicates a high degree of participation, whether the pupils belong to the official age group or not. A rate value approaching or exceeding 100% indicates that a country is, in principle, able to accommodate all of its school-age population, but it does not indicate the proportion already enrolled. The achievement of a rate of 100% is therefore a necessary but not sufficient condition for enrolling all eligible children in school. This is one of the limitations of this indicator: the gross enrolment rate can exceed 100% due to the inclusion of over-aged and under-aged pupils because of early or late entrants, and grade repetition. In this case, a rigorous interpretation of the enrolment rate needs additional information to assess the extent of repetition, late entrants, etc. (Source: UNESCO Institute for Statistics glossary).

Data availability

The UNESCO Statistics Institute regularly collects data to estimate secondary enrolment gross rates, by country and by year. Most recent data are provided by the Data Centre. More historical data are available online in the category *Key statistical tables on education*.

■ Data Centre data

Frequency of data on secondary enrolment rate, gross and net, provided by the Data Centre:

Period	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008
Nb countries, gross	159	167	168	175	176	175	172	154	160	75
Nb countries, net	103	118	114	124	120	120	126	108	115	49
Before 1999: no observation										

■ Key statistical tables on education

Table 22 provides historical data on secondary education for many countries, every five years over 1970-2005.

Method

Data Centre data are utilized as a primary source, and historical data as a secondary source. First, primary data are interpolated in order to fill in the gaps between two values; when it is not possible, secondary data are used for the interpolation.

The FOS HAI dataset is constituted of these data. The following methods concern only the WFG HAI dataset computation.

■ Method no. 1

For values missing in the ending parts of time series, imputation for the missing values is based on estimating the following model, which includes income level, lagged value of secondary enrolment, and time and region fixed effects. The OLS estimator is used:

$$(3.4.1) \text{ } SEG_{it} = \alpha_1 + \beta_1 \cdot \ln(GNI_{it}) + \gamma_1 \cdot SEG_{i,t-1} + \delta_{1t} \cdot t_t + \mu_{1i} \cdot region_i + \varepsilon_{1it}$$

The secondary enrolment gross ratio is then generated, chronologically and year after year:

$$(3.4.2) \widehat{SEG}_{it} = \alpha_1 + \beta_1 \cdot \ln(GNI_{it}) + \gamma_1 \cdot SEG_{i,t-1} + \delta_{1t} \cdot t_t + \mu_{1i} \cdot region_i$$

■ Method no. 2

For values missing in the beginning parts of time series, we generate values for the missing values by first estimating the following model, which includes income level, future value of secondary enrolment, and time and region fixed effects. The OLS estimator is used:

$$(3.4.3) \text{ } SEG_{it} = \alpha_2 + \beta_2 \cdot \ln(GNI_{it}) + \gamma_2 \cdot SEG_{i,t+1} + \delta_{2t} \cdot t_t + \mu_{2i} \cdot region_i + \varepsilon_{2it}$$

The secondary enrolment gross ratio is then generated, ante-chronologically and year after year:

$$(3.4.4) \widehat{SEG}_{it} = \alpha_2 + \beta_2 \cdot \ln(GNI_{it}) + \gamma_2 \cdot SEG_{i,t+1} + \delta_{2t} \cdot t_t + \mu_{2i} \cdot region_i$$

■ Method no. 3

The beginning part of the Eritrea time series is assessed by using the relative deviation from Ethiopia series. Indeed, Eritrea and Ethiopia constituted a single country for years; and all their series do look alike. We first calculate an average ratio between Eritrea secondary enrolment and Ethiopia secondary enrolment over 1995-2008 (years for which Eritrea has information on its secondary enrolment rate):

$$(3.4.5) \text{ } Ratio = \frac{1}{14} \sum_{t=1995}^{t=2008} \frac{SEG_{Erytrea,t}}{SEG_{Ethiopia,t}}$$

We then apply this ratio on Eritrea to generate values over 1970-1994:

$$(3.4.6) \text{ } SEG_{Eritrea,t} = ratio \cdot SEG_{Ethiopia,t}$$

Table D.5 (in appendix D) presents the results for estimates of models (3.4.1) and (3.4.3), i.e. for methods no. 1 and 2.

■ Method no. 9

Method no. 9 concerns missing values that cannot be generated:

- Azerbaijan, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Lithuania, Latvia, Moldova and Uzbekistan from 1970 to 1979;
- Armenia, Tajikistan, Timor-Leste from 1970 to 1989;
- Montenegro, North Korea, Turkmenistan.

4 Results: the HAI retrospective data

After having applied all methods described in section 3, two HAI datasets are now available: an incomplete dataset, called “From Official Sources HAI – FOS HAI”; and a more complete dataset, called “With Filled Gaps HAI – WFG HAI”. Since the WFG HAI series are completed with generated values from econometric estimates using as explanatory variables the GNI per capita, the Gini coefficient, time effects and country or region effects, we advise to use them for econometric analyses only very cautiously. For that purpose, it should be better to utilize FOS HAI series, which cannot generate the same endogeneity bias.

4.1 *An enlarged panel of countries and a new time horizon...*

It is now possible to make HAI comparisons across a larger number of countries than ever before. We now have HAI data for 147 countries (see the list of countries Table C.1, appendix C), i.e. overall 15 additional countries compared to the UN CDP “HAI 2009 review”. Specifically, there are 27 new countries, and 12 removed countries, the latter including 11 high income countries and the Democratic People’s Republic of Korea (cf. Table 4.1).

The 147 countries include all 49 Least Developed Countries. The distribution across regions is as following: 22 countries from East Asia and Pacific (EAP), 24 countries from Europe and Central Asia (ECA), 32 countries from Latin America and Caribbean (LAC), 14 countries from the Middle East and North Africa (MENA), 8 countries from South Asia (SA) and 47 countries from Sub-Saharan Africa (SSA).

Finally, both FOS and WFG HAI datasets cover 1970-2008. This time extension is the main contribution of this work since the HAI data provided by the UN CDP are not panelized over time. These new databases now allow realizing time comparisons that have been until now very limited.

Table 4.1 Added and removed countries in the HAI retrospective database, compared to the HAI 2009 review

Added countries	LICs	Kyrgyzstan, Moldova, Tajikistan, Uzbekistan
	LMICs	Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Fed. St. Micronesia, FYRO Macedonia, Georgia, Kazakhstan, Marshall Isl., Romania, Serbia, Ukraine, West Bank and Gaza
	UMICs	Croatia, Estonia, Hungary, Latvia, Lithuania, Palau, Poland, Russia
Removed countries	LICs	Democratic People’s Republic of Korea
	HICs	Bahamas, Bahrain, Brunei Darussalam, Cyprus, Israel, Republic of Korea, Malta, Qatar, Saudi Arabia, Singapore, United Arab Emirates

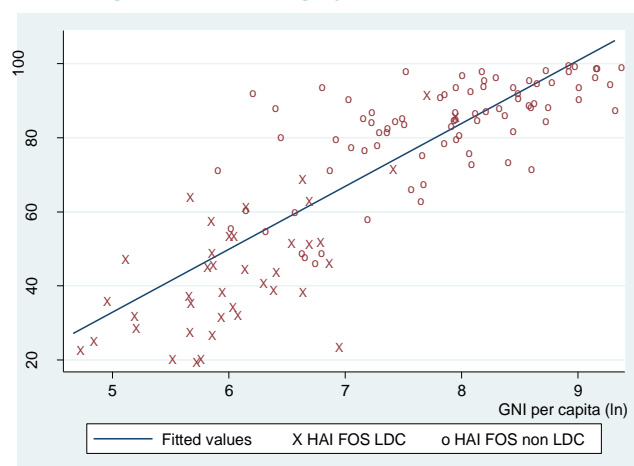

4.2 *... allow a more complete cross-country analysis...*

A low level of human capital is a key handicap to development. The HAI measures this level through an arithmetic average of four indices: the child mortality rate index (CS), the prevalence of undernourishment index (CI), the literacy rate index (LR), and the secondary enrolment gross rate index (SE). The four indices composing the HAI and the HAI itself are bounded between 0 and 100: 0 reflects the lowest level and 100 the highest reachable level. The mean level of HAI across the 147 countries over 2000-2008 is 72 (Table 4.2)

Generally, low income countries are less endowed with human capital

Table 4.2 indicates that low income countries have lower HAI levels (about 50) than upper-middle income countries (about 92) on average over 2000-08. Indeed, as suggests as well by the Figure 4.1, human capital level increases with income level. This trend can be observed with all indices composing the HAI (Table 4.2).

Figure 4.1. HAI level expressed as a function of the GNI per capita level (in ln) according to the LDC category membership, 2000-2008

Source: FOS HAI dataset

Least Developed Countries suffer much more

HAI is significantly lower in LDCs⁵. Indeed, the average of HAI in LDCs equals 48 in 2000s; it reaches 67 in low income but not least developed countries (Table 4.2). Kernel curves (Figure 4.2) also indicate such a difference: the diverse peaks reveal the division in human capital between LDCs and other low income countries and middle income countries. The same assessment appears for previous periods (Table 4.3), though a divergence of HAI levels seems to occur among LDCs whereas non LDCs converge towards better levels (Figure 4.3). Besides, when HAI level is represented as a function of GNI per capita, one can observe that most of LDCs dots are below the linear regression. This means that for a given income, LDCs produce lower levels of HAI than non LDCs.

This gap in human assets between LDCs and other countries is also perceivable for each HAI component (Table 4.2). In 2000s, child mortality rate amounted 128 in LDCs against 38 in other developing countries and 84 in other low income countries. The prevalence of undernourishment reaches 29% in LDCs and 10% in other developing countries and 21% in other low income countries. Divergences are also observed in education variables: 61% of literate people on average in LDCs versus 89% in other developing countries and 79% in other low income countries; the secondary enrolment rate goes from 33% on average in LDCs to 78% in other developing countries⁶.

Least Developed countries are logically at the bottom of the HAI ranking: 84% of the 30% lowest HAI level countries are LDCs (Table 4.4).

Differences across regions

Sub-Saharan African is unsurprisingly the region with the weakest HAI levels. Composed with a number of least developed countries, SSA has an average HAI score of only 48 in the 2000s. South Asia countries HAI score is higher (59 on average), mainly thanks to better health and nutrition (Table 4.2). Both regions are behind North Africa and Middle East (79), East Asia and Pacific (80), Latin America and Caribbean (86) and Europe and Central Asia (94). Same patterns are observed for previous periods (Table 4.3).

⁵ LDCs here correspond to countries classified as LDCs in 2010 by United Nations (cf. list Table C.2, Appendix C).

⁶ In each case, differences are statistically significant (with a 1% confidence interval).

4.3 ... and a more consistent analysis of the evolution over time

Globally, human capital level has progressed since 1970s

We find an improvement of the HAI over all countries from 1970 with 44 to 2008 with 74 (Figure 4.4). This increase can be observed in all regions and income groups, as well as for all the indices composing the HAI (Table 4.5).

Figure 4.4 Evolution of the HAI and its components

Source: WFG HAI database

In 2005-08, the contribution of each component to the HAI seems to be balanced, contrasting with before: in 1970-74, the prevalence of undernourishment index (CI) contributed much more to a high HAI level than the other indices (CS, LR, and especially SE). These latter components have relatively progressed better than CI since the 1970s (cf. Figures 4.5 and 4.6).

Generally, all HAI components have been improved from 1970-74 to 2005-08 (Table 4.5 and Figure 4.4): child mortality rate was reduced to half, with 141 in 1970-74 and 63 in 2005-08; the literacy rate was increased from 56% of literate in 1970-74 and 81% in 2005-08; finally, the secondary enrolment rate has progressed by +36% points, from 30% in 1970-74 to 66% in 2005-04. The prevalence of undernourishment was also reduced, even in a lesser extent, from 24% in 1970-74 to 16% in 2005-08⁷.

An obvious progress in LDCs

Despite limited resources and extremely low initial level of HAI, the LDCs have progressed rapidly from 1970-74 to 2005-08. Indeed, HAI progressively increased from 23 to 50 on average (cf. Figure 4.7). All HAI components have been improved: child mortality decreased by 108 per thousand live births (from 228 to 120); literacy rate increased by 30 percentage points (33% to 63%); secondary enrolment rate increased by 26 percentage points (11% to 37%). Only undernourishment showed a small improvement, with a decrease of 6 percentage point only (cf. Table 4.5).

But not necessary a convergence towards other countries levels

Do these gains allow a reduction of human capital gaps between LDCs and other countries? We could expect a convergence in human capital level like for income per capita level in the standard neoclassical growth model⁸. All the more, HAI levels are naturally bounded, so that all countries might more or less rapidly converge to upper bounds. This point however represents a methodological problem: convergence might be measured either by the reduction of the absolute difference in HAI over time, or by a relative difference, or by a relative difference of the distance to the upper bound⁹. For a discussion on the methodology, please refer to *Caught in a Trap*, chapter 5, BOX 5.3: *How to measure change and convergence in human capital indicators* (Guillaumont 2009).

⁸ In these models, income growth is more rapid for low initial income countries (because of decreasing returns of capital).

⁹ The distance between HAI and the upper bound (100) can be considered as a human handicap index.

Figure 4.7 Evolution of HAI over time: LDCs vs non LDCs

Source: WFG HAI database

Using the absolute differences in HAI, we do not observe convergence between low-income countries and higher income countries, neither between least developed countries and non least developed countries: the absolute differences in HAI between sub-periods are almost identical (+30 pts) according to the income group or to the LDC category membership¹⁰ (cf. Table 4.5 and Table E.3 in the Appendix E). On the contrary, regarding the relative differences in HAI, we notice a certain convergence (Tables E.1 and E.4 in Appendix E): relative progresses in HAI for LDCs are more important than for all LICs¹¹. On the other hand, using the relative difference of the distances to the upper bound (cf. Table E.2), data show divergence¹².

That said, it seems that, for a same initial level, LDCs converge less rapidly than other countries. Figure 4 suggests that, for LDCs, the absolute difference of HAI between 1970-74 and 2005-08 is the same whatever the initial level is. The same conclusions emerge when using logistical forms of HAI (Fig. 4.9).

Figure 4.8 Absolute difference of HAI between 1970-74 and 2005-08, as a linear function of the HAI of 1970-74, LDCs versus non LDCs

Figure 4.9 Absolute difference of the Logit of HAI between 1970-74 and 2005-08, as a linear function of the Logit of HAI of 1970-74, LDCs versus non LDCs

Source: WFG HAI dataset

¹⁰ Difference not statistically different even when considering LDCs versus low-income countries non LDCs.

¹¹ The difference is statistically significant. This convergence was expected since LDCs initial levels are lower and that there is no absolute divergence.

¹² The difference is statistically significant. This “divergence” was also expected since LDCs initial distances to HAI are more important and that there is no absolute convergence.

Child mortality and literacy rate are the components that contribute the most to convergence in HAI levels

Child mortality and literacy rates have experienced a better improvement in LDCs than in non LDCs (cf. Tables 4.5, E.6, E.8 and Figure 4.10). Indeed, child mortality rate in LDCs was 228 on average in 1970-74 and decreased to 120 on average in 2005-08 (-118 points). In non LDCs it decreased from 99 in 1970-74 to 34 in 2005-08 (-65 points). This convergence is visible in Figure 4.10, but figures allow noticing it more obviously, particularly with the absolute and relative differences (Tables 4.5 and E.1)^{13,14}.

Literacy rate increased by 30% points on average in LDCs between 1970-74 and 2005-08. Developing countries non LDCs experienced a lower improvement, with an increase of 22 % points.

Whereas the secondary enrolment rate seems to contribute much more to divergence

On the contrary, the secondary enrolment gross rate improved less rapidly in LDCs than in non LDCs: in LDCs it increased from 11% to 37% on average between 1970-74 and 2005-08 (+26 % points); in non LDCs it increased from 40% to 80% (+40% points). This divergence is perceptible on Figure 4.11, and when looking at absolute differences (Table 4.5) and relative differences to the distance to the upper bound (Table E.2). However, we rather observe convergence when looking at the relative differences (Table E.1)¹⁵.

Finally, we do not notify significant difference between LDCs and other countries regarding the prevalence of undernourishment, that rises from 34% to 28% on average between 1970-74 and 2005-08 in LDCs (-6 % points); and from 19% to 10% in non LDCs (-9 points).

Figure 4.10 Evolution of under-five mortality rate according to the membership to LDCs

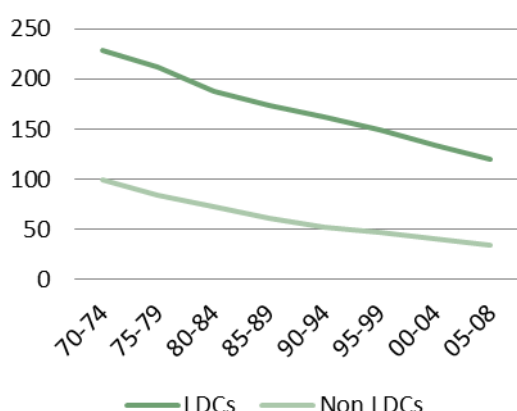

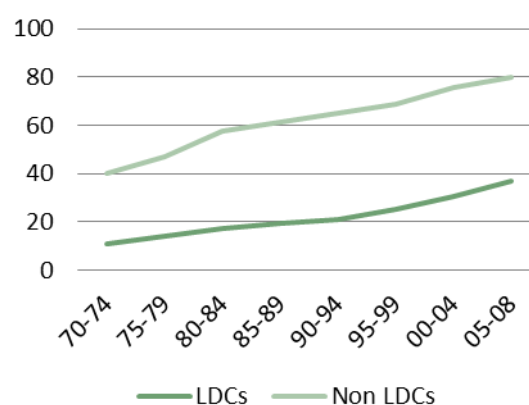

Figure 4.11 Evolution of the secondary enrolment gross rate, according to the membership to LDCs

Source: WFG HAI database

Different trends are perceptible also across the different regions of the world

The weakest improvements in absolute difference concern Europe and Central Asia. This is mainly the result of ex-USSR countries HAI evolution, such as Tajikistan, Armenia, Georgia, Azerbaijan and Uzbekistan that stagnate, and even Tajikistan that decreases. These countries are among those that observed the most important decline in their HAI ranking¹⁶. Other countries experienced important

¹³ The differences are statistically significant.

¹⁴ This is not the case when looking at the relative differences of the distance to the upper bound.

¹⁵ The differences are statistically significant.

¹⁶ This might be due to the decline in the prevalence of undernourishment in USSR countries. It is to be noted that for ex-USSR countries and over 1970-1989, the prevalence of undernourishment is compiled from the average kilocalories levels of USSR ; consequently, the prevalence of undernourishment might be overestimated in some of these countries for this period, and then the difference between 1970-74 and 2005-08 might be underestimated.

declines such as North Korea, Nauru, Mongolia, Panama, and Micronesia. For these countries, the HAI level stagnated or hardly reduced, whereas the general trend was increasing.

The highest increase in absolute is realized by Middle East and North Africa countries. They experienced great improvements in all components, education, health and nutrition. The countries which progress the better in the ranking between the 1970s and the 2000s are Algeria (+39 ranks), Iran (+30 ranks), Tunisia (+37 ranks), Turkey (+33 ranks), Oman (+73 ranks) and Libya (+50 ranks).

5 Conclusion

This working paper presents the methods applied for the computation of retrospective panel HAI datasets that cover a large time period and a number of countries unseen until now: 147 countries between 1970 and 2008. These datasets are available on the FERDI website (www.ferdi.fr) and/or on request. For a rapid lookup, HAI and its components data are provided for each country and for each ten-year period in the Appendix F.

HAI is a human capital index used for the identification of least developed countries; it corresponds to the average of four indexes dealing with child mortality, prevalence of undernourishment, literacy and secondary enrolment.

Using existing retrospective data on these four components as well as estimating prevalence of undernourishment with average daily energy supply in kilocalories per capita, allowed us to build the "From Official Sources HAI dataset" (FOS HAI). These data contain information on 123 countries over 1970-2008, and can be used for advanced statistical analyses. However, this dataset is not complete neither balanced. Among other things, older values are frequently missing. This led us to estimate these missing values and to build a second dataset, called "With Filled Gaps HAI" (WFG HAI), with an almost balanced panel for 147 countries over 1970-2008. Before using these series for a statistical analyses purpose, it is important to understand the way they have been computed. This paper explains this in its section 3.

We find that least developed countries suffer much more from a lack of human assets over 1970-2008. In spite of great improvements over the whole period, the HAI levels did not converge towards those of non LDCs. Indeed, HAI improved over all region and income groups, and neither convergence nor divergence can be observed.

Bangladesh	India	Nepal	Sri Lanka

Note: because of a lack of initial data, countries marked with * do not provide figures on HAI but provide information on some HAI components.

Table C.1 (continuation)

Sub-Saharan Africa - SSA

Angola	Cote d'Ivoire	Madagascar	Seychelles
Benin	Equatorial Guinea	Malawi	Sierra Leone
Botswana	Eritrea	Mali	Somalia
Burkina Faso	Ethiopia	Mauritania	South Africa
Burundi	Gabon	Mauritius	Sudan
Cameroon	Gambia	Mozambique	Swaziland
Cape Verde	Ghana	Namibia	Tanzania
Central African Rep.	Guinea	Niger	Togo
Chad	Guinea-Bissau	Nigeria	Uganda
Comoros	Kenya	Rwanda	Zambia
Congo	Lesotho	Sao Tome and Principe	Zimbabwe
Congo, Dem. Rep.	Liberia	Senegal	

Note: because of a lack of initial data, countries marked with * do not provide figures on HAI but provide information on some HAI components.

Table C.2 List of Least Developed Countries

Afghanistan	Equatorial Guinea	Malawi	Sierra Leone
Angola	Eritrea	Maldives	Solomon Islands
Bangladesh	Ethiopia	Mali	Somalia
Benin	Gambia	Mauritania	Sudan
Bhutan	Guinea	Mozambique	Tanzania
Burkina Faso	Guinea-Bissau	Myanmar	Timor-Leste
Burundi	Haiti	Nepal	Togo
Cambodia	Kiribati	Niger	Tuvalu
Central African Rep.	Laos	Rwanda	Uganda
Chad	Lesotho	Samoa	Vanuatu
Comoros	Liberia	Sao Tome and Principe	Yemen
Congo, Dem. Rep.	Madagascar	Senegal	Zambia
Djibouti			

Table C.3 List of Small Island Developing States

Antigua and Barbuda	Grenada	Micronesia	Suriname
Barbados	Guinea-Bissau	Palau	Timor-Leste
Belize	Guyana	Papua New Guinea	Tonga
Cape Verde	Haiti	St Kitts and Nevis	Trinidad and Tobago
Comoros	Jamaica	St Lucia	Tuvalu
Cuba	Kiribati	St Vincent and Gren.	Vanuatu
Dominica	Maldives	Sao Tome and Principe	
Dominican Rep.	Marshall Islands	Seychelles	
Fiji	Mauritius	Solomon Islands

Notes: Income class and LDCs groups used are those applicable in 2005-09. Upper bound is considered as the “best outcome”: this bound corresponds to 1 for HAI, CS, CI, LR, and SE, to 10 for under five mortality (U5M), to 2.5 for the prevalence of undernourishment (PREV), and to 100 for literacy rate (LIT) and secondary gross enrollment rate (SE gross).
